Practice Midterm

Problem 1

Let $H \leq G$ and $A \leq G$ such that $|G : H| = 3$ and $|A| = 85$. Prove that

1. $A \leq H$.
2. $\cap_{g \in G} g^{-1}Hg \neq 1$.

Solution:

Part A

Observe that the right cosets of H partitions G into equivalent classes, so $x \sim y \iff xy^{-1} \in H$.
(Why? say $x, y \in Hb$ for some $b \in G$, then $x = h_1b$ and $y = h_2b$ then

$$xy^{-1} = h_1b(h_2b)^{-1} \quad (1)$$

$$= h_1bb^{-1}h_2^{-1} \quad (2)$$

$$= h_1h_2^{-1} \in H \quad (3)$$

Thus, if we restrict this partition into equivalent class to A , it's still a partition. Let $u, v \in A$, since $A \cap H \leq A$, we have u, v in some coset w.r.t. $A \cap H \iff uv^{-1} \in A \cap H$ which means uv^{-1} in A and in H .
since uv^{-1} is automatically in A because A is a group,

$$uv^{-1} \in A \cap H \iff uv^{-1} \in H \quad (4)$$

$$\iff u, v \text{ in the same coset w.r.t. } H \text{ in } G \quad (5)$$

This observation implies the number of $A \cap H$ cosets in A is at most the # of H cosets in G , which is 3, since $|G : H| = 3$.

Since # of $A \cap H$ cosets in A need to divide the order of $|A| = 85$, this number cannot be 3 or 2, so it must be 1. Thus, $|A : A \cap H| = 1$, and since $A \cap H \leq A$, we conclude $A \cap H = A \implies A \cap H \supseteq A$ which implies $A \leq H$.

Part B

We show $a \in \cap_{g \in G} g^{-1}Hg$. Take any $a \in A$. Observe that if we let \mathcal{R} be the set of all right cosets of H , then for $g \in G$, we define $g^\rho \in \text{Sym}\mathcal{R} = S_3$ by $g^\rho : Hx \mapsto Hxg$ then $\rho : G \xrightarrow{\rho} \text{Sym}\mathcal{R} = S_3$ is a homomorphism because $g \rightarrow g^\rho$. and $g \in G$ is acting on the right cosets of H in G by right multiplication, and $\ker \rho = \cap_{g \in G} g^{-1}Hg$.

If $x \in \cap_{g \in G} g^{-1}Hg$, then for all cosets of H, Hb , we can write $x = b^{-1}h_1b$ for some $h_1 \in H$. So $Hb \rightarrow Hbx = Hbb^{-1}h_1b = Hh_1b = Hb$, which is the identity permutation, so $x \in \ker \rho$ implies $\ker \rho \supseteq \cap_{g \in G} g^{-1}Hg$. If $x \in \ker \rho$, then for all Hb , we have $Hb = Hbx \implies H = Hbxb^{-1}$, thus, $bx b^{-1} \in H \implies bx b^{-1} = h_2$ for some $h_2 \in H$.

$$\implies x = b^{-1}h_2b \in \cap_{g \in G} g^{-1}Hg$$

$$\implies \ker \rho \subseteq \cap_{g \in G} g^{-1}Hg$$

Thus, $\ker \rho = \cap_{g \in G} g^{-1}Hg$.

We show for any $a \in A, a \in \ker \rho$. Let $a \in A \implies |a| \mid |A| = 85$, Also $|\rho(a)|$ divide $|S_3| = 3! = 6$.

Let $|a| = k$, so $a^k = 1$.

then $(\rho(a))^k = \rho(a^k) = \rho(1) = 1$, so $|\rho(a)|$ divide k .

Thus, $|\rho(a)|$ divide $\gcd(85, 6) = 1$.

so $|\rho(a)| = 1 \implies \rho(a) = 1$

so a is in $\ker \rho$.

Thus, $A \subseteq \ker \rho$, so $\ker \rho \neq 1 \implies \cap_{g \in G} g^{-1}Hg \neq 1$.

Problem 2

Assume that $\langle c \rangle \triangleleft G$, $|G : \langle c \rangle| = 3$, c has infinite order, and some $b \in G$ has order 3. Prove that $G = \langle c, b \rangle$ and $G \cong \mathbb{Z}^+ \times \mathbb{Z}_3^+$. (For any ring S , the additive group of S is denoted by S^+ .)

Solution:

$\langle c \rangle \triangleleft G$, $|G : \langle c \rangle| = 3$, since $\langle c \rangle$ is infinite cyclic group (c has infinite order), any element that is non identity has infinite order. Thus, $b \notin \langle c \rangle$, since $|b| = 3$.

Thus, we can form distinct cosets $\langle c \rangle$, $b\langle c \rangle$, $b^2\langle c \rangle$.

$b\langle c \rangle$ and $b^2\langle c \rangle$ are distinct, since if $b\langle c \rangle = b^2\langle c \rangle$, then $b^{-1}b^2 \in \langle c \rangle$,

$\implies b \in \langle c \rangle$. Contradiction.

Since $|G : \langle c \rangle| = 3$, we found all $\langle c \rangle$ cosets.

since G is partitioned into cosets, we have $G = \langle c \rangle \cup b\langle c \rangle \cup b^2\langle c \rangle$, and elements $g \in G$ is in one of the cosets, and can be written as $b^i c^j$, and since $\langle c \rangle \triangleleft G$, the left, right cosets of $\langle c \rangle$ in G are the same, so G is indeed generated by $\langle c, b \rangle$.

It's clear that $\langle c \rangle \triangleleft G$, $\langle b \rangle \cap \langle c \rangle = 1$, and since G is generated by $\langle c, b \rangle$, and $\langle c \rangle$ is normal, so $\langle b \rangle \cdot \langle c \rangle$ is a group, so $\langle b \rangle \cdot \langle c \rangle \leq G$. but any $g \in G$ can be written as $b^i c^j$, if it's $c^j b^i$, then use normality of $\langle c \rangle$ to get $b^i c^{j'}$. Thus, we only need to show $\langle b \rangle \triangleleft G$, then G is the internal direct product of $\langle c \rangle$ and $\langle b \rangle$, so it's isomorphic to the external direct product $\langle c \rangle \times \langle b \rangle$, then since $\langle c \rangle \times \langle b \rangle \cong \mathbb{Z}^+ \times \mathbb{Z}_3^+$, by sending $c \mapsto 1$ in \mathbb{Z}^+ , and $b \mapsto 1$ in \mathbb{Z}_3^+ .

so $G \cong \langle c \rangle \times \langle b \rangle \cong \mathbb{Z}^+ \times \mathbb{Z}_3^+$.

Show $\langle b \rangle \triangleleft G$.

Problem 3

Prove that \mathbb{Q}^+ (the additive group of the rational numbers) is hopfian.

Hint. If $H \leq \mathbb{Q}^+$ and $|H| > 1 \implies \exists n \in H$ such that n is a positive integer and $\frac{1}{n} \notin H$. Then $\frac{1}{n} + H$ has finite order in \mathbb{Q}^+/H .

Solution:

We want to show take any subgroup that is not 1, and not \mathbb{Q}^+ , $H \leq \mathbb{Q}^+$, then $\mathbb{Q}^+/H \not\cong \mathbb{Q}^+$.

since \mathbb{Q}^+ is abelian, any subgroup is normal.

Thus, we take a proper $H \leq \mathbb{Q}^+$, $H \neq \mathbb{Q}^+$, $|H| > 1$, observe that $|H| = \infty$, since if $h \neq e, h \in H$, then all $(h + h + h + \dots)$ with $nh \in H$, so H has infinite many elements. Thus, for some sufficient large positive integer $m \in H$, we have $1/m \notin H$. This is possible since $H \neq \mathbb{Q}^+$. Thus, we could consider coset $1/m + H$. This coset has finite order in \mathbb{Q}^+/H , since $m^2(\frac{1}{m} + H) = m^2 \frac{1}{m} + H = m + H = H$, so $|\frac{1}{m} + H|$ divides m^2 , so $|\frac{1}{m} + H| < \infty$. However, every non identity element $q \in \mathbb{Q}^+$ has infinite order, since adding q to itself many times will never get to zero. Thus, there cannot be an isomorphism between $\frac{\mathbb{Q}^+}{H}$ and \mathbb{Q}^+ , since Isomorphism preserves order of the element. We can also obtain a direct contradiction. say $\exists \phi: \frac{\mathbb{Q}^+}{H} \rightarrow \mathbb{Q}^+$. such that $\phi(\frac{1}{m} + H) = q \in \mathbb{Q}$ and $q \neq 1$. Let $|\frac{1}{m} + H| = k < \infty$, then $1 = \phi(1) = \phi((\frac{1}{m} + H)^k) = \phi(\frac{1}{m} + H)^k = q^k$ thus q has finite order. Contradiction.

Problem 4

Let a group G have order $5^2 \cdot 7 \cdot 37$. Show that

1. G has a unique Sylow 37-subgroup \mathbb{Q} .
2. $Q \leq Z(G)$.
3. The mapping $f : G \rightarrow G, \forall g \in G, g \rightarrow g^{175}$ is a homomorphism. What is the image of f ?

Solution:

G has order $5^2 \cdot 7 \cdot 37$, show G has unique Sylow 37-subgroup Q , let $n_{37} = \#$ of Sylow 37 subgroup in G , by Sylow theorem,

$$n_{37} \equiv 1 \pmod{37} \text{ and} \quad (6)$$

$$n_{37} \text{ divide } 5^2 \cdot 7 = 175, \quad (7)$$

possible choices: 1, 5, 7, 25, 35, 175, but among those, only 1 satisfy $1 \equiv 1 \pmod{37}$. so $n_{37} = 1$, so G has unique Sylow 37 subgroup, we call \mathbb{Q} .

Part A

G acts on \mathbb{Q} by conjugation, and since unique Sylow- p subgroup is also normal, $\mathbb{Q} \triangleleft G$, thus, $\forall g \in G, g^{-1}Qg \subseteq Q$, and since $h^{-1}(g^{-1}Qg)h = (gh)^{-1}Qgh$, this conjugation action could be associated with automorphism on Q .

$$G \xrightarrow{\varphi} \text{Aut}(Q) \leq \text{Sym}(Q) \quad (8)$$

$$g \xrightarrow{\varphi} fg \text{ where } Q^{fg} = g^{-1}Qg \subset Q \quad (9)$$

similar to a proof in class, $Q \leq Z(G) \iff$ this action is trivial $\iff \varphi$ is trivial: φ maps G to the identity automorphism on Q .

$$\iff \text{Im}\varphi = \{e\}.$$

Thus, we show $Q \leq Z(G)$ by showing $\text{Im}\varphi = \{e\}$. By 1st Iso Thm

$$G/\ker\varphi \cong \text{Im}\varphi \implies \frac{|G|}{|\ker\varphi|} = |\text{Im}\varphi| \implies |\text{Im}\varphi| \text{ divide } |G| = 5^2 \cdot 7 \cdot 37 \quad (10)$$

On the other hand, $\text{Im}\varphi \leq \text{Aut}(Q)$.

Since $|Q| = 37$, which is prime $\implies Q$ is cyclic $\implies Q$ is abelian.

thus, except identity, all elements of Q has order 37, and there are 36 of such elements, so $|\text{Aut}(Q)| = 36$.

Let $Q = \langle a \rangle$.

$$37 = \text{order}(a^i) = \frac{\text{order}(a) = 37}{\gcd(37, i)} \implies \gcd(37, i) = 1 \quad (11)$$

implies there are 36 such i satisfy this.

Thus, $|\text{Im}\varphi|$ divide $|\text{Aut}(Q)| = 36$.

Thus, $|\text{Im}\varphi|$ divide both 36 and $5^2 \cdot 7 \cdot 37$

$$\implies |\text{Im}\varphi| \text{ divide } \gcd(36, 5^2 \cdot 7 \cdot 37) = 1 \implies |\text{Im}\varphi| = 1 \implies \text{Im}\varphi = \{e\}.$$

Part B

Since Q is the unique Sylow 37 subgroup, Q is normal, so get factor group $|G/Q| = 175$, since $\text{Im}f = \{g^{175} \mid g \in G\}$. Let $g \in G$

$$Qg^{175} = (Qg)^{175} = e_{G/Q} = Q \quad (12)$$

which implies $g^{175} \in Q$, $\implies \text{Im}f \subset Q$. Since f is homomorphism, *why?* $\text{Im}f$ is a subgroup of $G \implies \text{Im}f \leq Q$, thus, $|\text{Im}f|$ divide $|Q| = 37 \implies |\text{Im}f| = 1$ or 37 .

Assume $|\text{Im}f| = 1 \implies \text{Im}f = \{e\} \implies \{g^{175} | g \in G\} = \{e\}$, so for all $g \in G, g^{175} = e \implies |g|$ divide 175 , but we know $e \neq q \in Q$ has order 37 since Q is prime order cyclic group, and $37 \nmid 175$. Contradiction.
 $\implies |\text{Im}f| = 37$. Combine with $\text{Im}f \leq Q \implies \text{Im}f = Q$.

Consider the action of G on the set of right cosets of $A : \mathcal{R}$

$$G \xrightarrow{\rho} \text{Sym}\mathcal{R} \quad (13)$$

$$g \rightarrow g^\rho \quad (14)$$

$$g^\rho : Ab \rightarrow Abg \quad (15)$$

By 1st iso thm:

$$G/\ker\rho \cong \text{Im}\rho \leq S_5 \quad (16)$$

$$|G/\ker\rho| = |\text{Im}\rho| \text{ divide } |S_5| = 5! = 120 \quad (17)$$

first, observe that $\ker\rho$ cannot be the whole group G , because if $\rho(G) = 1$, then this contradicts ρ action transitively on the five cosets of A in G .

If $|G| > 5!$ then since $|G/\ker\rho|$ divides $5!$, we conclude $\ker\rho > 1$. So we are done in this case.

If $|G| \leq 5!$, then we observe if we let $|G| = k \leq 5!$, k must have a factor of 5 , since $|G : A| = 5$, $\implies 5 \mid k$. Thus, there exists a Sylow 5 -group, we call S .

If $\#$ of S is 1 , we are done, since unique S is normal.

If $\#$ of S is not 1 , let's consider it's possibilities.

$$\# \text{ of } S \equiv 1 \pmod{5} \quad (18)$$

$$\# \text{ of } S \mid \frac{k}{5}, \quad (19)$$

$$\frac{k}{5} \leq \frac{120}{5} = 24 \quad (20)$$

Since $\frac{k}{5}$ can be any number in $\{1, 2, \dots, 24\}$,
 $\#$ of S could be $6, 11, 17, 22$.

If $\#$ of S is 6 , then we consider Syl_3 subgroup in A , since $|A|$ has a factor of 3 . (because $6 \mid \frac{k}{5}$). Then since Syl_3 subgroup are conjugates of each other, if $\exists!$ Syl_3 subgroup, we done, if not, there are 5 of them, because there are 5 cosets of A , but $5 \equiv 2 \pmod{3}$, which is a contradiction, so $\exists!$ Syl_3 subgroup which is normal. Other case can be done similarly.

for p instead of 3 , provided $5 \not\equiv 1 \pmod{p}$, i.e., $p \neq 2$.

Problem 5

Let G be a group (infinite or finite). Let $A \neq 1$ be an abelian subgroup of G such that $|G : A| = 5$. Show that G has some nontrivial normal subgroup.
